

# Transfer Statements:

## Break Statement:

- **Definition:** The `break` statement is used to exit a loop prematurely. When encountered, it immediately terminates the loop, and control passes to the next statement outside the loop.
- **Use Case:** Useful when a specific condition is met, and there is no need to continue the loop.

Syntax:

```
for item in iterable:  
    if condition:  
        break
```

- **Related Statement:**

- **Definition:** There isn't a directly related statement to `break`. However, it is often used in conjunction with conditional statements (`if`) to determine when the loop should be terminated.

Example:

```
for i in range(5):  
    if i == 3:  
        break  
    print(i)
```

## An Example with Break and its Related Statement:

- **Scenario:**
  - We want to iterate through a list and stop when we encounter a specific element.

```
numbers = [1, 2, 3, 4, 5]
```

```
for num in numbers:  
    if num == 3:
```

```
        print("Found 3, breaking loop.")
        break
    print(num)
```

### Continue:

- **Definition:** The `continue` statement is used to skip the rest of the code inside a loop for the current iteration and move to the next iteration.
- **Use Case:** Useful when a specific condition is met, and you want to skip the remaining code for the current iteration but continue with the next iteration.

Syntax:

```
for item in iterable:
    if condition:
        continue
    # code here will be skipped if the condition is met
```

### Pass:

- **Definition:** The `pass` statement is a null operation, meaning it does nothing. It acts as a placeholder where syntactically some code is required, but you don't want to perform any action.
- **Use Case:** Useful when a statement is syntactically required but no action is desired.

Syntax:

```
if condition:
    pass
```

### Notes:

- Indentation is critical for proper code structure in Python.
- The `break` statement is used to exit a loop prematurely.
- `continue` is employed to skip the rest of the code for the current iteration and move to the next one.

- `pass` is a placeholder statement with no effect, useful when syntactically some code is required but no action is needed.
